Introduction to Supervised Learning

Problem setup, feature types, assumptions about data

Machine Learning and Data Mining, 2025

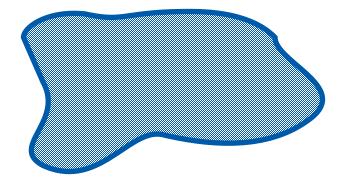

Majid Sohrabi

National Research University Higher School of Economics

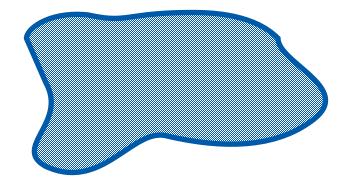

Supervised Learning

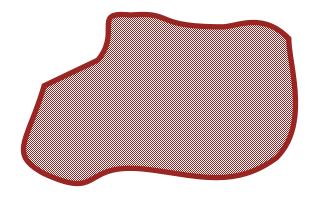

X – a set of objects

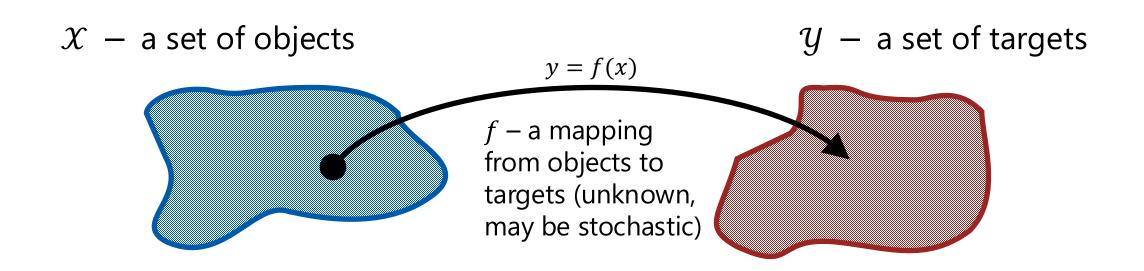

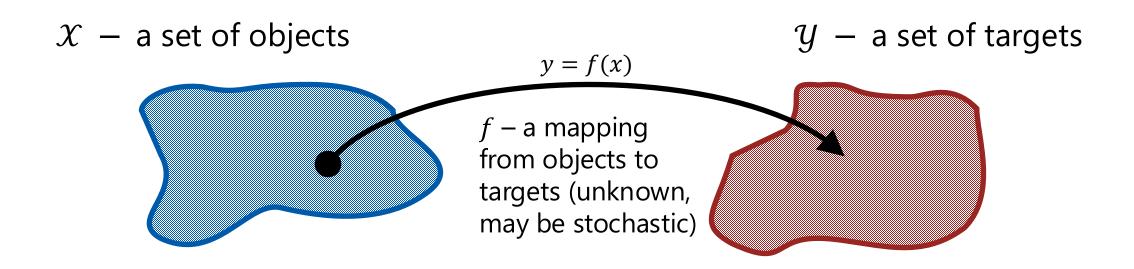

X – a set of objects

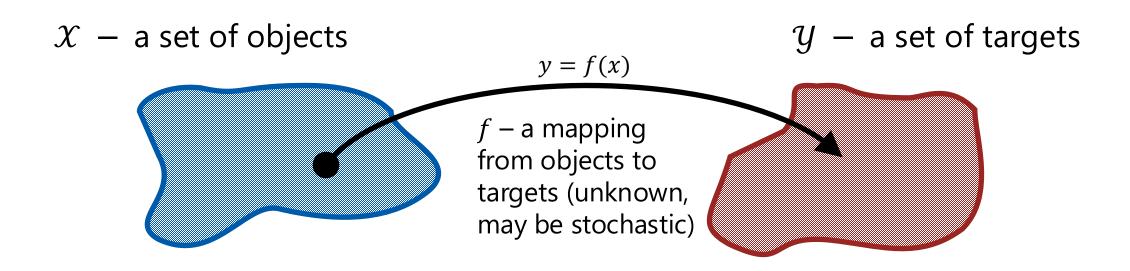

y – a set of targets

A dataset:
$$D = \{(x_i, y_i) : i = 1, 2, ..., N\}$$
 $x_i \in \mathcal{X}, \quad y_i = f(x_i) \in \mathcal{Y}$

A dataset:
$$D = \{(x_i, y_i) : i = 1, 2, ..., N\}$$

$$x_i \in \mathcal{X}, \qquad y_i = f(x_i) \in \mathcal{Y}$$

Goal: approximate f given D

i.e. learn to recover targets from objects

Examples

Iris flower species classification

Objects

Individual flowers, described by the length and width of their sepals and petals

Targets

Species to which this particular flower belongs

Mapping

Different shapes of sepals and petals correspond to different species

(non-deterministic)

images source: wikipedia.org

Examples

Spam filtering

Objects

E-mails (sequences of characters)

Targets

"spam" / "not spam"

Mapping

Message content defines whether it's spam or not

(non-deterministic, varies from person to person)

Examples

CAPTCHA recognition

Objects

CAPTCHA images (vectors of pixel brightness levels)

Targets

Sequences of characters

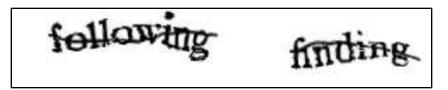

image source: wikipedia.org

Mapping

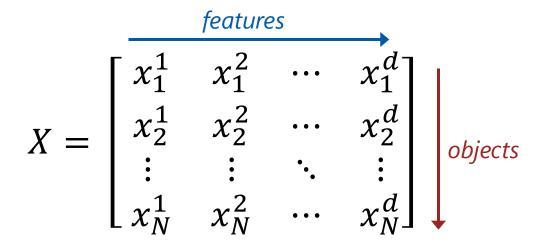

Inverse of CAPTCHA generating algorithm

(almost deterministic, depending on the level of distortion)

- ▶ Objects x_i are described by features x_i^j , i.e.:
 - It's a vector $x_i = (x_i^1, x_i^2, ..., x_i^d)$

- ▶ Objects x_i are described by features x_i^j , i.e.:
 - It's a vector $x_i = (x_i^1, x_i^2, ..., x_i^d)$
- many algorithms require that the dimensionality d of the data is same for all objects

- ▶ Objects x_i are described by features x_i^j , i.e.:
 - It's a vector $x_i = (x_i^1, x_i^2, ..., x_i^d)$
- many algorithms require that the dimensionality d of the data is same for all objects
 - In such case the objects may be organised in a design matrix:

Example: Iris dataset

| ^ ^ |
|-----|
| 0.2 |
| 0.2 |
| 0.2 |
| 0.2 |
| 0.2 |
| |
| 2.3 |
| 1.9 |
| 2.0 |
| 2.3 |
| 1.8 |
| |

In this example, all featuers are real numbers

Feature types

- Individual features x_i^j may be of various nature
- Common cases:
 - Numeric features, e.g.:
 - Sepal length
 - Height of a building
 - Temperature
 - Price
 - Age
 - Etc.

Feature types

- Individual features x_i^j may be of various nature
- Common cases:
 - Categorical

```
nominal (no order implied), e.g.:
```

Color City of birth Name **ordinal** (values can be compared, though pairwise differences are not defined), e.g.:

Level of education Age category (child, teen, adult, etc.)

Feature types

- Individual features x_i^j may be of various nature
- Common cases:
 - **Binary**, e.g.:
 - True / False
 - Can be treated as numeric (0/1 or -1/+1)

One-hot encoding

How does one convert categorical feature to numeric?

One-hot encoding

- How does one convert categorical feature to numeric?
 - Assigning each category a number (e.g. "red" = 1, "green" = 2, etc.) may
 have negative effect on the learning algorithm

One-hot encoding

- How does one convert categorical feature to numeric?
 - Assigning each category a number (e.g. "red" = 1, "green" = 2, etc.) may have negative effect on the learning algorithm
- One-hot encoding simple trick to convert categorical feature to numeric:

| color | | is_blue | is_red | is_green |
|---------|----------|---------|--------|----------|
| "red" | | 0 | 1 | 0 |
| "red" | | 0 | 1 | 0 |
| "blue" | ─ | 1 | 0 | 0 |
| "green" | | 0 | 0 | 1 |
| "blue" | | 1 | 0 | 0 |

A trick for ordinal features

One-hot encoding may be used, though it loses the information about the relations between the categories

A trick for ordinal features

- One-hot encoding may be used, though it loses the information about the relations between the categories
- Similar trick:

| Academic degree | | is_bachelor | is_master | is_PhD |
|-----------------|---------|-------------|-----------|--------|
| "none" | | 0 | 0 | 0 |
| "bachelor " | | 1 | 0 | 0 |
| "master" | | 1 | 1 | 0 |
| "PhD" | | 1 | 1 | 1 |
| "master" | | 1 | 1 | 0 |

More advanced encoding techniques

See https://contrib.scikit-learn.org/category encoders/index.html

Learning Algorithms

Machine Learning Algorithm

Algorithm A:

```
given a dataset D = \{(x_i, y_i) : i = 1, 2, ..., N\} x_i \in \mathcal{X}, y_i = f(x_i) \in \mathcal{Y}
```

returns an approximation $\hat{f} = \mathcal{A}(D)$ to the true dependence f.

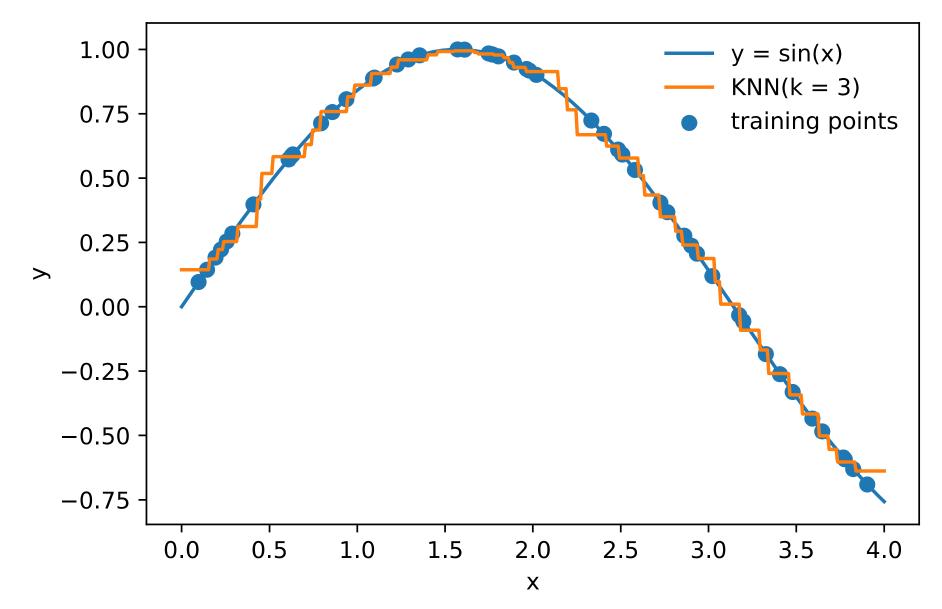

Example: k nearest neighbors (kNN)

- Idea: close objects should have similar targets
- Why don't we look up k closest (by some metric of the feature space) objects in the dataset and average their targets:

$$\hat{f}(x) = \frac{1}{k} \sum_{i: x_i \in D_x^k} y_i$$

 D_x^k – set of k objects from D closest to x

Example: k nearest neighbors

training points: 50

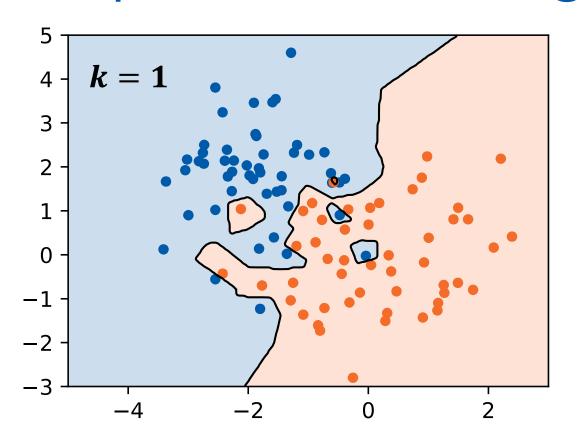

Example: k nearest neighbors

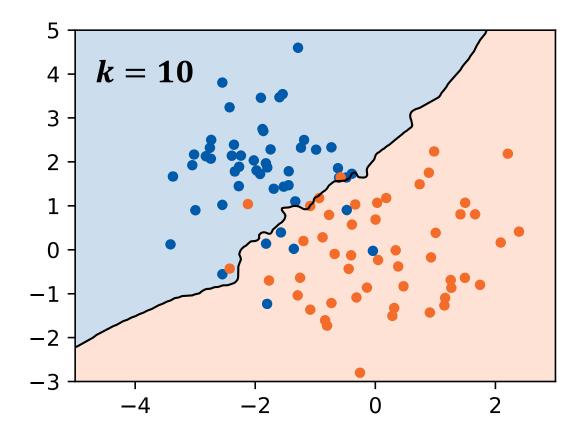

training points: 250

More data = better approximation

Example: k nearest neighbors

Classification example

$$\hat{f}(x) = \underset{C}{\operatorname{argmax}} \sum_{i: x_i \in D_x^k} \mathbb{I}[y_i = C]$$

 D_x^k – set of k objects from D closest to x

How does an algorithm find the approximation $\hat{f} = \mathcal{A}(D)$ to the true mapping function?

- How does an algorithm find the approximation $\hat{f} = \mathcal{A}(D)$ to the true mapping function?
- Many algorithms work by solving an optimization task

- How does an algorithm find the approximation $\hat{f} = \mathcal{A}(D)$ to the true mapping function?
- Many algorithms work by solving an **optimization task**
- We can measure the quality of a prediction for a single object x_i with a loss function $\mathcal{L} = \mathcal{L}(y_i, \hat{f}(x_i))$

E.g. squared error:

$$\mathcal{L} = \left(y_i - \hat{f}(x_i)\right)^2$$

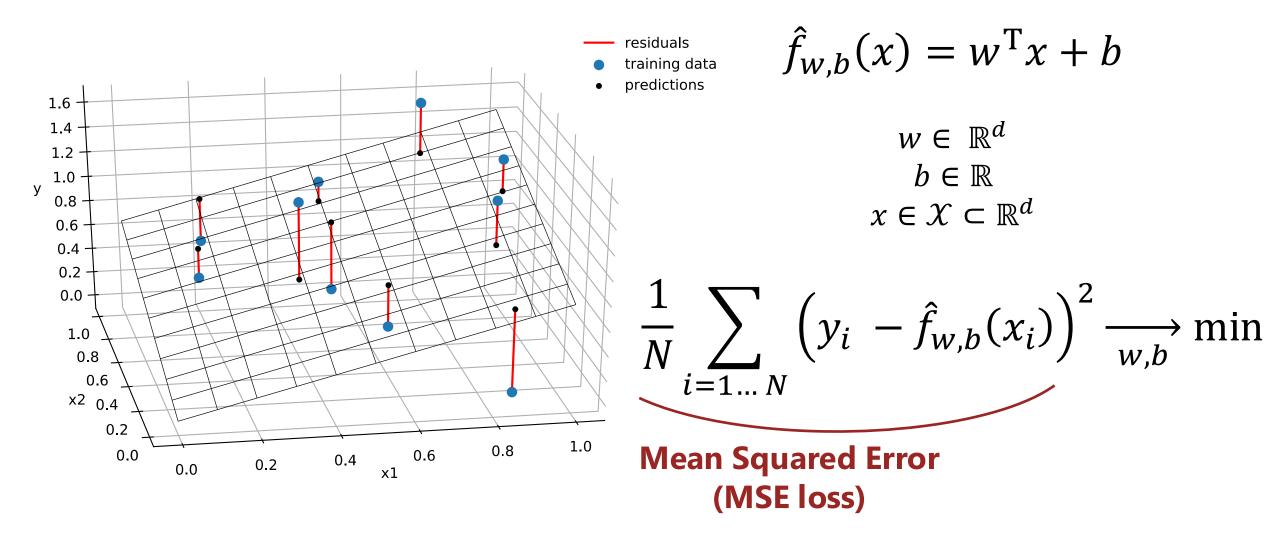

- How does an algorithm find the approximation $\hat{f} = \mathcal{A}(D)$ to the true mapping function?
- Many algorithms work by solving an optimization task
- We can measure the quality of a prediction for a single object x_i with a loss function $\mathcal{L} = \mathcal{L}(y_i, \hat{f}(x_i))$
- Then, learning (or training) can be formulated as a loss minimization problem:

$$\hat{f} = \underset{f}{\operatorname{argmin}} \mathbb{E}_{(x, y) \in D} \mathcal{L}(y, f(x))$$

E.g. squared error:

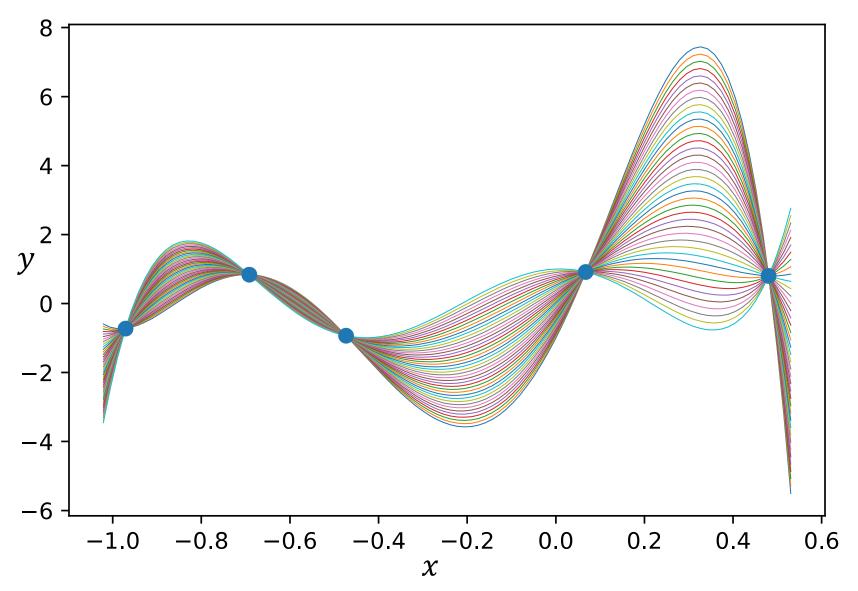

$$\mathcal{L} = \left(y_i - \hat{f}(x_i)\right)^2$$

Example: linear regression

Assumptions about data

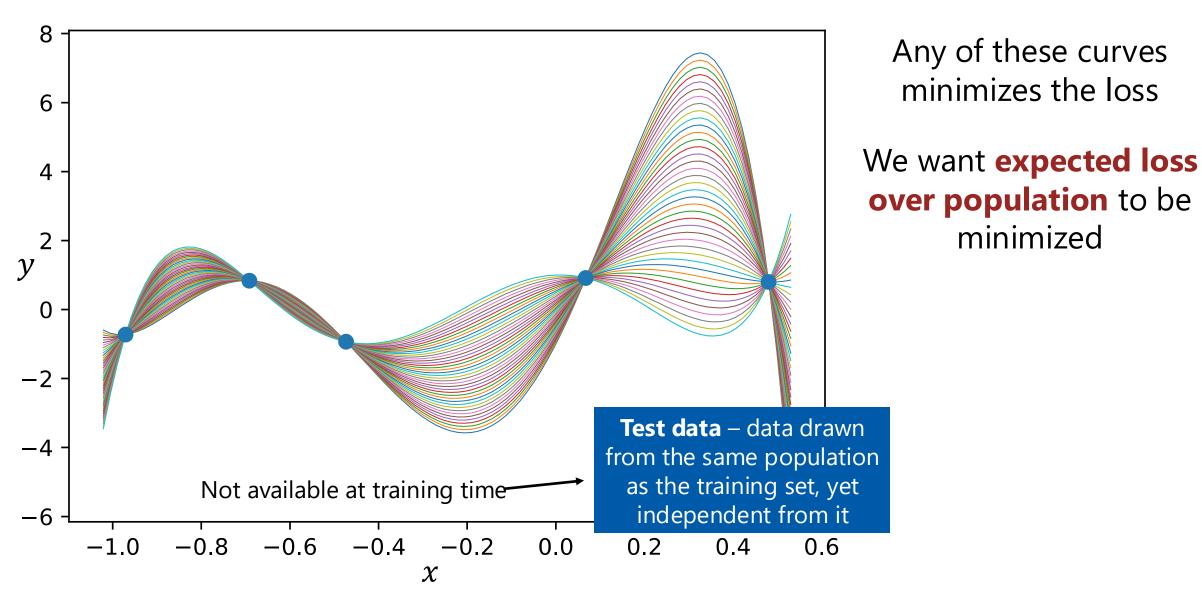

No assumptions = Infinitely many solutions

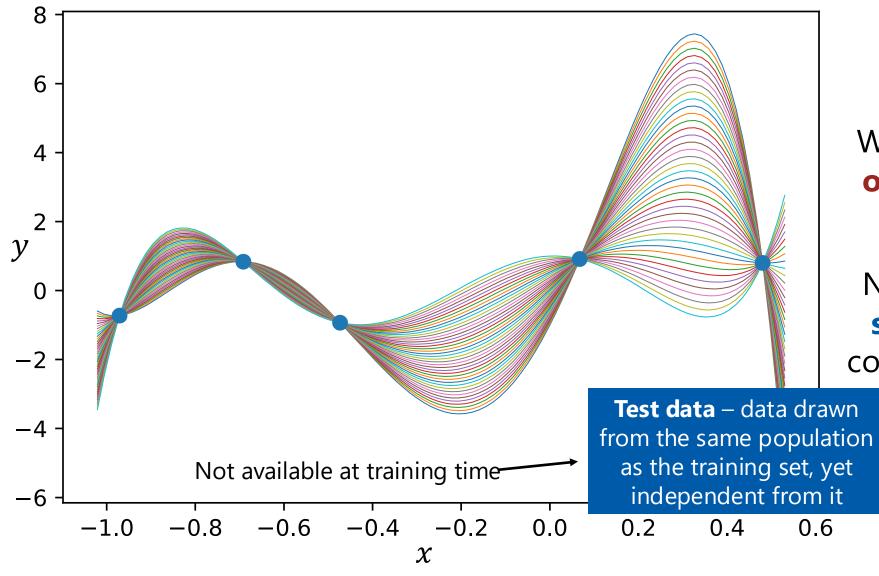

Any of these curves minimizes the loss

We want **expected loss over population** to be
minimized

No assumptions = Infinitely many solutions

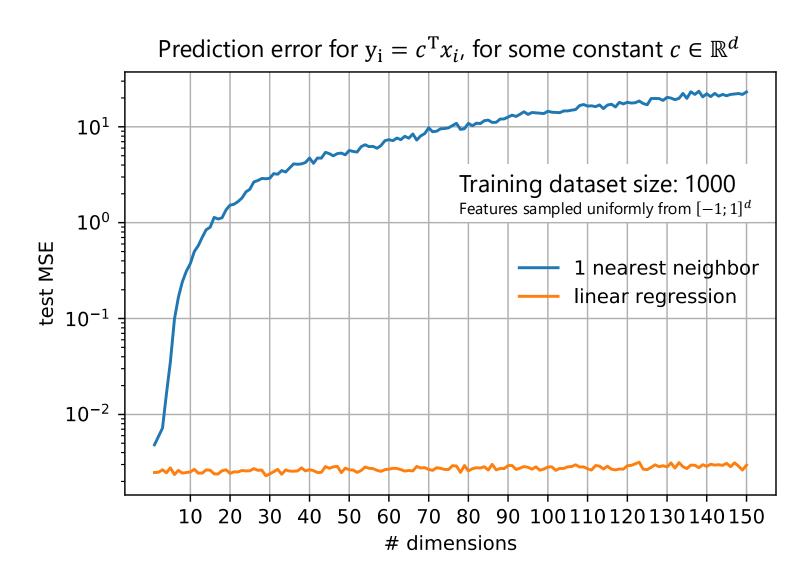

No assumptions = Infinitely many solutions

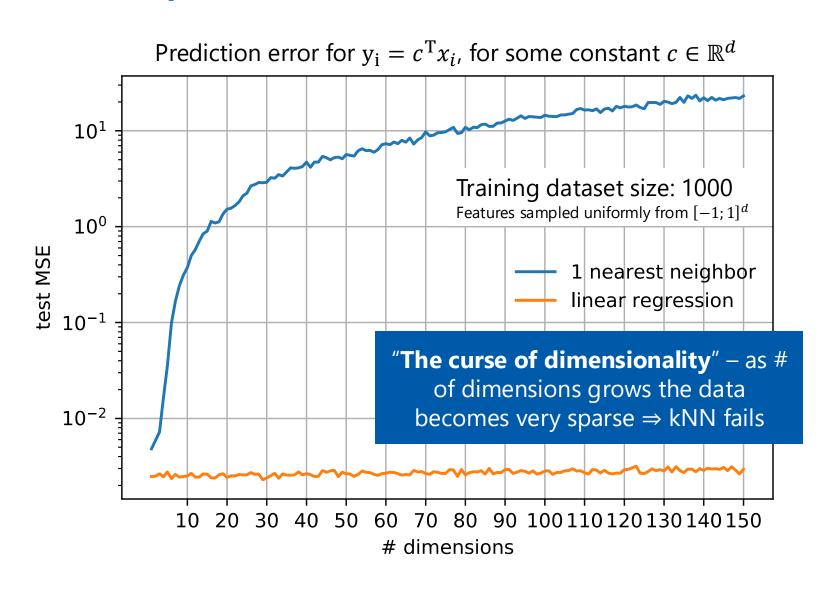

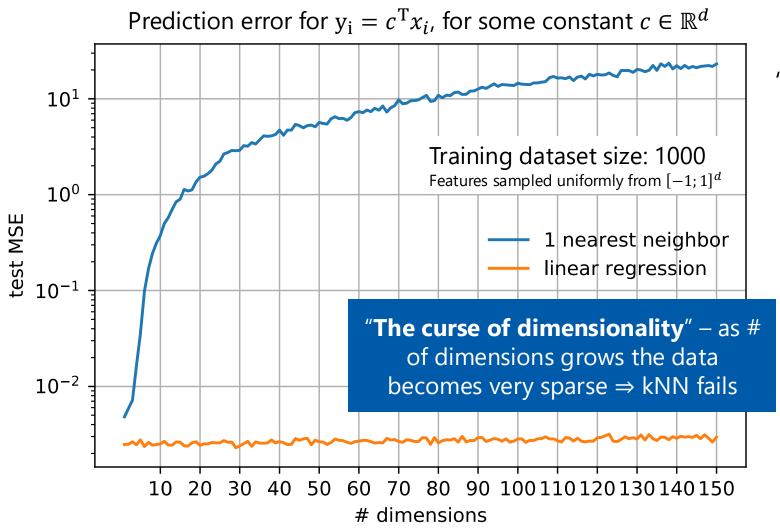

Any of these curves minimizes the loss

We want **expected loss over population** to be minimized

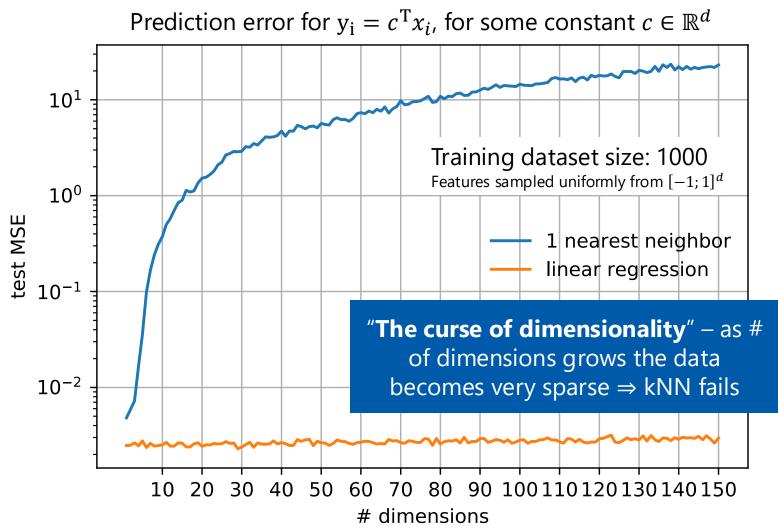

Need to assume some structure of the data, common to training and testing data

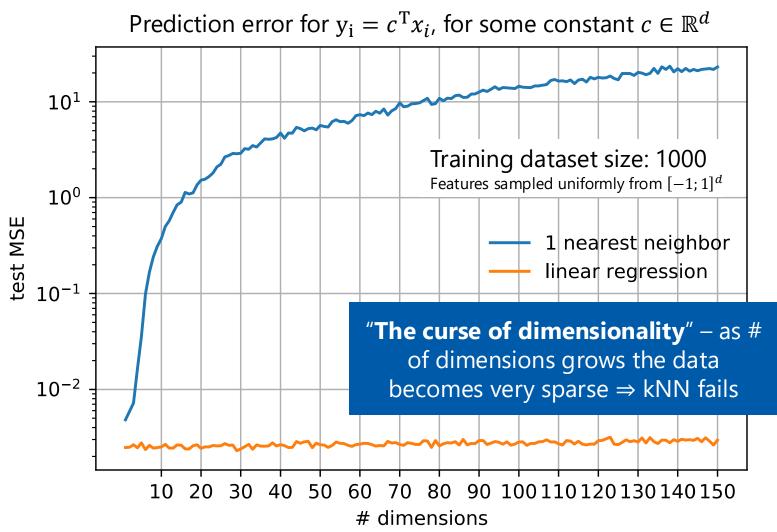

Assumption for kNN: "similar objects have similar targets"

Assumption for kNN: "similar objects have similar targets"

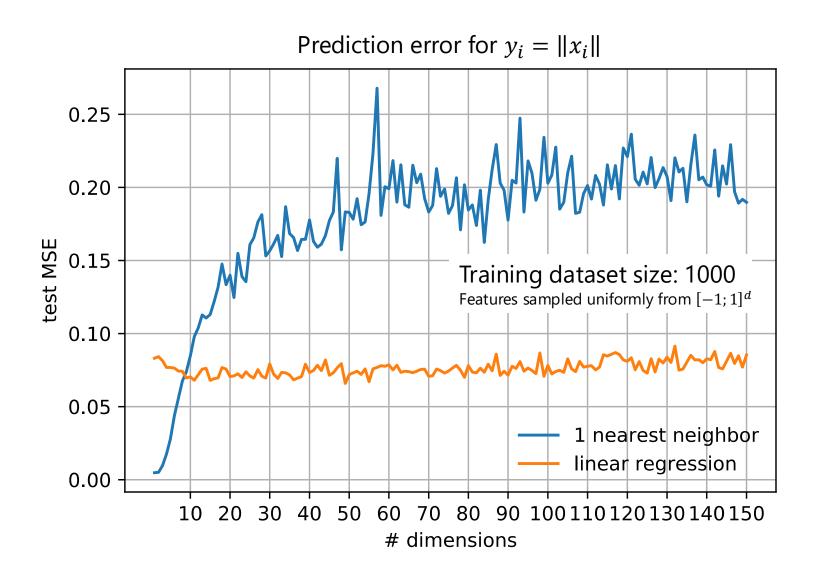

Assumption for Linear Regression: "targets are linear in features"

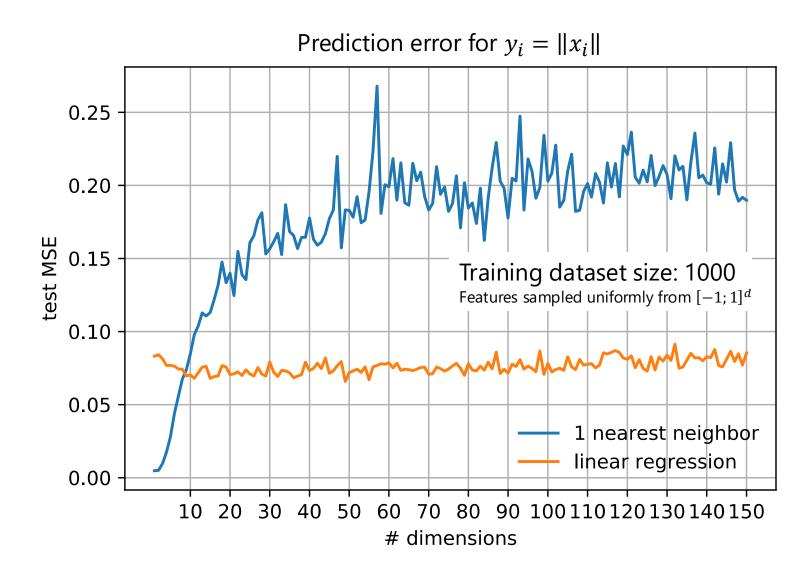

Assumption for kNN: "similar objects have similar targets"

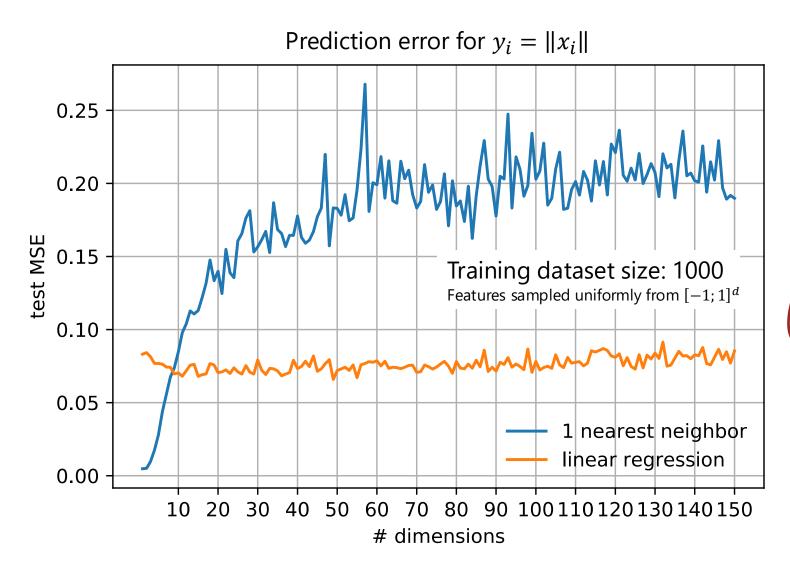

Assumption for Linear Regression: "targets are linear in features"

For this example, both assumptions are correct, but one is **stronger** than the other

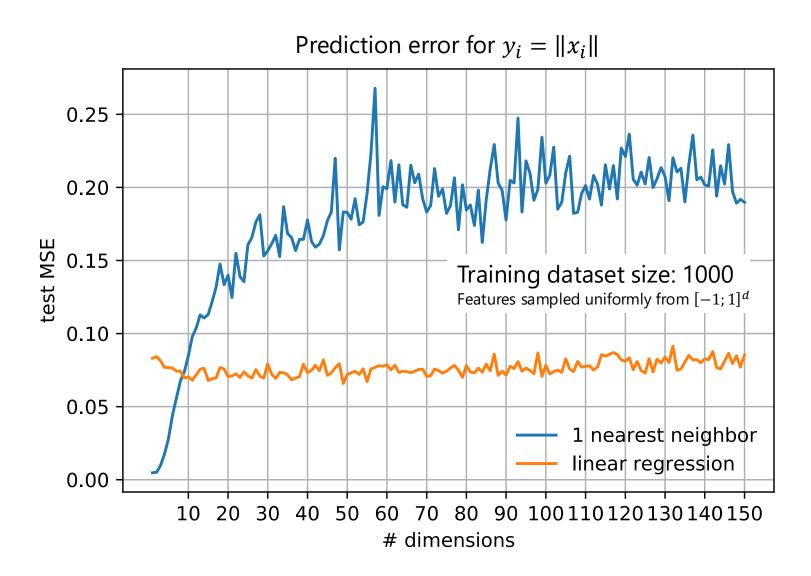

For this example, kNN assumption is still correct, while linearity assumption is invalid

For this example, kNN assumption is still correct, while linearity assumption is invalid

Imposing assumptions about the data restricts the space of possible solutions

$$\hat{f} = \underset{(x, y) \in D}{\operatorname{argmin}} \mathbb{E} \mathcal{L}(y, \tilde{f}(x))$$

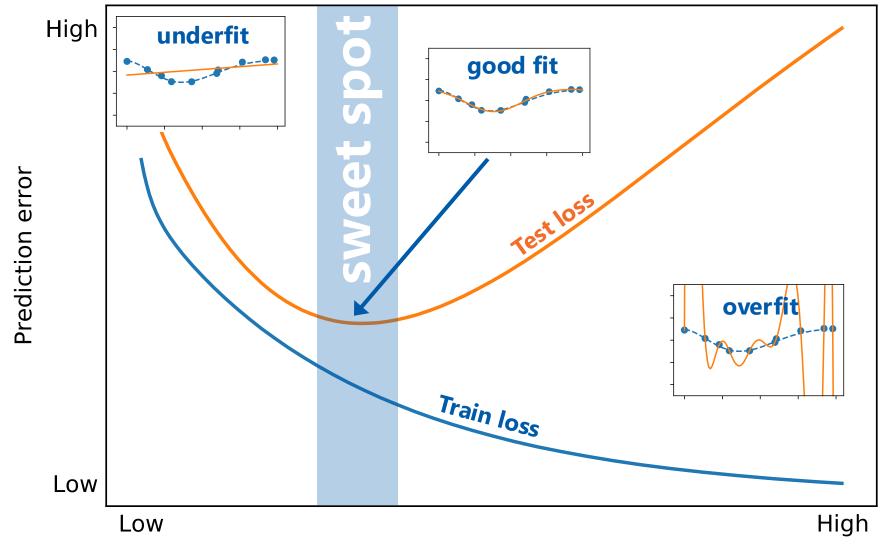

For this example, kNN assumption is still correct, while linearity assumption is invalid

Imposing assumptions about the data restricts the space of possible solutions

This restriction allows to **overcome the curse of dimensionality**

(Though, wrong assumptions lead to wrong solutions)

How to check whether a model is good?

Check the loss on the **test data** – i.e. data that the learning algorithm "hasn't seen"

The goal is to find the right level of limitations – not too strict, not too loose

Model Complexity
(~ size of the solution space)

Supervised Machine Learning algorithms build approximations $\hat{f} = \mathcal{A}(D)$ to the true dependence f

- Supervised Machine Learning algorithms build approximations $\hat{f} = \mathcal{A}(D)$ to the true dependence f
- Features may be of various nature, one-hot encoding is useful to convert categorical features to numeric

- Supervised Machine Learning algorithms build approximations $\hat{f} = \mathcal{A}(D)$ to the true dependence f
- Features may be of various nature, one-hot encoding is useful to convert categorical features to numeric
- Machine Learning algorithms can be defined as expected loss minimization tasks

- Supervised Machine Learning algorithms build approximations $\hat{f} = \mathcal{A}(D)$ to the true dependence f
- Features may be of various nature, one-hot encoding is useful to convert categorical features to numeric
- Machine Learning algorithms can be defined as expected loss minimization tasks
- Choosing the right model = applying the right assumptions about the data

- Supervised Machine Learning algorithms build approximations $\hat{f} = \mathcal{A}(D)$ to the true dependence f
- ► Features may be of various nature, one-hot encoding is useful to convert categorical features to numeric
- Machine Learning algorithms can be defined as expected loss minimization tasks
- Choosing the right model = applying the right assumptions about the data
- Use test data to detect underfitting and overfitting

- Supervised Machine Learning algorithms build approximations $\hat{f} = \mathcal{A}(D)$ to the true dependence f
- ► Features may be of various nature, one-hot encoding is useful to convert categorical features to numeric
- Machine Learning algorithms can be defined as expected loss minimization tasks
- Choosing the right model = applying the right assumptions about the data
- Use test data to detect underfitting and overfitting

► Food for thought: how can Linear Regression model be used to fit a n-th degree polynomial?

Thank you!
